OmniRoute Installation Guide

Windows • VS Code Terminal • Step by Step

Before you begin

This guide describes the npm-based installation flow. Confirm the package name and current instructions in the official OmniRoute documentation before running installation commands, because package names and setup steps can change.

Step 1: Open the VS Code terminal

Open Visual Studio Code, choose Terminal → New Terminal, and use PowerShell or Command Prompt.

Step 2: Install Node.js

Open the official Node.js download page, download the current LTS version for Windows, and run the installer using the default options. Close and reopen VS Code after installation.

```
node -v
npm -v
```

Both commands should print version numbers. If either command is not recognized, reopen the terminal or check that Node.js was added to PATH.

Step 3: Install OmniRoute

```
npm install -g omniroute
```

Run this only after confirming that the package on npm is the intended OmniRoute project and reviewing its current official instructions. Wait for npm to finish and read any errors shown in the terminal.

Step 4: Start OmniRoute

```
omniroute
```

If the command is available, start the service and keep that terminal open. If Windows reports that the command is not recognized, check the package documentation for the correct executable name and installation method.

Step 5: Open the local dashboard

If the application reports that its local dashboard runs at this address, open it in your browser:

```
http://localhost:20128
```

Do not assume this port is correct if the terminal shows a different address. Use the URL printed by the running application.

Step 6: Configure a provider

In the dashboard, open the provider or connections area, add a supported provider, and follow its authentication steps. Availability, free access, and API-key requirements depend on the provider.

Step 7: Connect a VS Code AI extension

If you want to use OmniRoute with an AI coding extension, follow the official integration instructions for that extension. Confirm the publisher and project documentation before installing an extension with a similar name.

Step 8: Test the local API (optional)

If the documentation confirms this endpoint and your configured API key, run the following in a second terminal. Replace YOUR_KEY with your own key. Never share the key publicly.

```
curl.exe http://localhost:20128/v1/models -H "Authorization: Bearer YOUR_KEY"
```

Troubleshooting

- **node or npm is not recognized:** Reinstall Node.js LTS if needed, then restart VS Code.
- **npm installation fails:** Read the full error output and verify the package name and official installation method.
- **omniroute is not recognized:** Check whether the package installed successfully and confirm its executable name.
- **Dashboard does not open:** Check the terminal for the actual local URL, port, and startup errors.
- **Provider fails:** Verify authentication, model access, and provider-specific requirements.

Security reminder: Keep API keys private. Only enter keys into software and providers you trust.
